Chapter 1

Introduction

I decided to compile a guide to the documentation of \LaTeX . Such a guide is needed, because there are many good works that can help a person to become erudite in \LaTeX , but they are not always obvious; and in every place where a good work is not found, a less satisfactory explanation stands.

This guide is accompanied by (and is a part of) a repository, which is available on github. The name of the repository is “A Beginner Guide To LaTeX Resources”.

<https://github.com/chrisgpj/A-Beginner-Guide-To-LaTeX-Resources>

A note on the text

In many places throughout this guide, I have used “LaTeX”, rather than “ \LaTeX ”. While “ \LaTeX ” is the official rendering, “LaTeX” is official within plain-text environments, and I prefer this in prose.

This booklet is *not* an introduction to LaTeX, and it is *not* to expound the virtues of LaTeX; such things have already been written. This booklet instead attempts to help people by directing them to documentations and resources that I wish I had used much earlier in my journey.

Chapter 2

L^AT_EX Documentation

Without good documentation, there is no such thing as a good system, or program, or whatever the *thing* is. It is my view that good documentation cannot save a bad project, but bad documentation can hamstring a good one.

If you read this chapter, you will arrive at the end with the knowledge of where to go to learn about L^AT_EX, where to lookup commands and markup, and where to go for tutorials on your very first documents.

However, it is necessary to speak briefly on L^AT_EX first, or else confusion will abound later-on. The following synopsis is the bare minimum.

2.1 The Structure of L^AT_EX

The place to begin is with T_EX.

T_EX was made by Donald Knuth to improve the typesetting-quality of academic articles and books, which he noticed to be in decline as then-new digital technologies were introduced into the workflow. An axiom of T_EX is that it is a *typesetting* program.

The manual typesetters of old had to forge a path from handwritten manuscripts to formatted print. They had to make decisions about what fonts to use, what types of words to make italic, how to format their chapter-breaks, and

so on. The manuscript would be ‘marked-up’ to communicate specific instances of typesetting action; an underlined word usually meant ‘make this italic’, for example. However, even with these steps completed, there was still work to be done in figuring out exactly how to execute those instructions — when to break to a new line, when to hyphenate a word, and such. Typesetters effectively calculated an optimum within the instructions they had for the text¹

The way TeX works is sometimes likened to the process of typesetting. The overall instructions and the markup for the text are written using the TeX language. The TeX program then takes those instructions and markup, transforming them into machine-readable instructions, and the engine runs calculations to optimise how the document is rendered. The output produced is usually in the form of a PDF (portable document format) file.

You will notice people referring to the different TeX components: the TeX markup/programming language, the TeX program, the TeX typesetting engine. As a whole, TeX is a system; these component are all part of a synchronous workflow. However, there is often call to consider these elements of the workflow separately. For one thing, the partitioning of the workflow is what makes possible the clarity of meaning that has made TeX so effective (as outlined in dot-points below).

TeX uses markup — quite a descriptive one. Applications of the idea of markup² — including TeX — really exploded in the early 80’s, although it had been around since 1969 with the invention of GML (Generalised Markup Language). The development of markup languages has been important for file encoding. For instance, the ‘x’ in the ‘.docx’ file extension stands for ‘XML’ (Exstensible Markup Language): XML is a descendant of GML. But for us, the focus is on typography. The idea behind markup is so simple it’s hard to explain. The hand-drawn underline indicating emphasis of a word adds meaning without transforming the word itself. In the same way, digital markup adds meaning without actually changing the original information. In most common word processors, italicising a word means it is also displayed in that form: the word is altered. TeX, however, uses plain-text

¹I believe that, to this day, we have not surpassed the technical excellence of the typesetters of the 19th century.

²In the digital sphere, that is.

and markup, so it does not conflate the original meaning and presentation. TeX is a ‘What You *Mean* is What You Get’ system, as opposed to a ‘What You *See* is What You Get’ system. The result achieved by TeX is a system that many people still consider to be the best option today, some forty years later.

Outside typographic professionals and programming professionals, most people use L^AT_EX, not T_EX. Up until this point, I have been talking about TeX, but I do not think the potential of TeX would have been realised without the advent of LaTeX.

LaTeX is a set of macros written for TeX by Leslie Lamport in the early 80’s (TeX had its origins in the 70’s!). In LaTeX, a few simple lines of code sets you up with a document that would be more complicated in TeX. You actually are using TeX in the background, and the typesetting engine is still a TeX engine; you’re just using a few LaTeX commands to represent many more TeX commands. If little customisation is introduced to a LaTeX document, it will naturally resemble one of the base templates (that is: of the sets of default macros), but it is quite easy to customise the document from this baseline, and in many cases you will interweave a few commands in base TeX language. Because LaTeX can streamline many parts of the process, we can more easily harness the idea of markup and focus effort where it belongs: on the text itself.

People use LaTeX today because:

- The typography is excellent. There are many reasons behind this, but one not mentioned yet is that the algorithms for calculating things like kerning — the spacing between letters and words — is good.
- You can use markup and commands to indicate formatting, meaning that the content (that is: your writing) is separate from the presentation.
- The input file is plain-text, which comes with a number of advantages, including stability of the file.
- Being able to ‘say what you mean’, rather than going through a ‘what you see is what you get’ system, creates clarity and precision.

- It is relatively easy to produce things like tables of contents, bibliographies, and cross-references. Because of this, *LaTeX* is considered ideal for thesis-writing.
- Logical structure of documents can be clearly specified, which can be helpful for denser and/or longer documents.
- The typeset is produced from the plain-text file by the engine, so there is less tendency to fiddle with the end-format; interventions have to be specified in text. The documents are less prone to become sensitive to small shifts of things like pictures or tables.
- Many packages have been written over time, extending the functionality of *LaTeX*.
- *TeX* and *LaTeX* are a part of the open-source sphere. The systems are maintained and extended with the help of a vast, highly-skilled community³.

Official Documentation, or Just Offal?

Knuth wrote a manual for *TeX*, just as he has written many books on computer programming. Some people have noted that this is not exactly for a general audience, because it teaches programmers how to typeset, rather than teaching the *TeX* programming language. However, we need not worry about these things, because we are using *LaTeX*.

Lamport wrote a manual, “*LaTeX: A Document Preparation System*”. Even though it is from 1985, that book is, for the most part, viable. However, very few people seem to use it. It is barely ever referenced on forums, and I suspect that it has simply not been made accessible enough for it to remain at the top of the recommended resource list. The community has stepped in with other resources, some of which are written by people who have made excellent packages for *LaTeX* and have been deeply involved in its maintenance. I feel that the absence of ‘official documentation’ explains some of the difficulty that people have in learning *LaTeX*. I hope that this guide saves some time and stress in that regard.

³See *XeTeX*, for example.

2.2 A couple of Favourite Documentations

So, what has the community produced and made available for free? From what I can see, probably everything you need.

Memoir

One of my favourite contributions is the memoir class documentation. In my own mind, this is the official documentation for LaTeX.

Now, the document class is the *very first thing* you tell LaTeX. It corresponds to the TeX macros that you are working with as your baseline. Memoir is the most popular and well-liked class for writing books and theses. It is the class I use, because it has great specifications for page sizes and margins, and these are things I need to consider when binding. The documentation for memoir is so good that it is well-regarded as a general documentation for LaTeX by the broader community. However, some things in it are specific to the class.

The memoir documentation is in the repository, in the “Documentations” folder.

I like it because it is comprehensive, well-explained, sensitive to broader concepts and theories while still being detailed, does not make too many assumptions about your circumstances, and has excellent cross-referencing to other resources. It is quite long, because of how deep thorough some of the explanations are.

I advise you to look at the memoir documentation, but not necessarily to use it as your first starting point. I know that you are a wonderful, intelligent, trailblazing scientist, but one of the below recommendations will still serve you well as the first step; memoir is something to come back to later, especially if you ever work in a book format.

A Not So Short Introduction

The “Not So Short Introduction to LaTeX” is a well-established reference guide and introduction to LaTeX. I like it because it acts as a reference book, but then does not skim over things too fast. It genuinely introduces

you to LaTeX by carefully thinking about the sorts of things that new LaTeX users would find useful. Consequently, it is indeed not very short — but that is why such things have chapters and a table of contents.

I recommend this guide as one of your possible starting points. It will provide you with a good introduction, good reference material, and it will help you to write concise code from the outset.

The bibliography for the *Note So Short Introduction* is an excellent list of publications and documentations.

Overleaf

Continuing our journey to a good beginning-point: Overleaf. Now, Overleaf is not really a documentation source. It is a website that offers a free, online LaTeX editor, and has some pretty good tutorial/reference-guides available as well. I think that you will get on quite well starting with the overleaf editor if you do not have something like VS Code set up; without such a set-up, LaTeX can get a bit overwhelming.

But my purpose here is to examine the documentation side of things. Overleaf has documentation, the first part of which is a tutorial ambitiously named “learn LaTeX in 30 minutes”. This is a good place to start if you want to get going. However, as you move forwards, you should transition to also using things like the ‘Not So Short Introduction’, and the memoir class documentation. These documentations are essentially whole books at your disposal. They are more comprehensive than overleaf, and allow some more space to get around LaTeX in a structured way.

I like overleaf because it is aware of the symbiotic role it plays in the LaTeX community by supplying these beginning points.

https://www.overleaf.com/learn/latex/Learn_LaTeX_in_30_minutes

2.3 Summary So Far

- *T*_E*X* can mean a typesetting language, program, or engine; or all at once (and by reading elsewhere you will discover much more nuance in the components of the *T*_E*X*).
- *L*^A*T*_E*X* is a streamlined way of working with *T*_E*X*
- A well-made online platform, with documentation, like overleaf is not a bad place to start, but you should have more cogent resources on hand as well. Setting up your own workflow is also essential — some discussion on this is provided elsewhere in the repository.
- The ‘Not So Short Introduction’ is excellent as both introduction and reference book.
- The memoir class documentation is excellent, and provides an in-depth walk-through of one of *LaTeX*’s most useful classes. Understanding memoir will help you to understand *LaTeX* at a deeper level.
- *L*^A*T*_E*X* is an interesting case of a program where the closest thing to the official documentation is not widely used. This has led to a nebulous certainty about where one should go, and that is why I have written this guide. Some documentations provided in this chapter are suitable for beginners, yet are impressively comprehensive, written at a high level by people who have contributed to *LaTeX*.

2.4 Other Documentations

XeTeX

LaTeX predates the compatibility of character encoding and fonts that we now take for granted. Character encoding has been particularly important for programs being able to work for multiple languages.

Because the initial *LaTeX* system predates things like Unicode, new engines have been built that to achieve compatibility. One advantage of these new engines is that they can use a wider array of fonts. Most *LaTeX* users are actually using variations, usually *XeTeX* or *LuaTeX*. I use *XeTeX*, as it

seems to be the most comprehensive option, and I have not encountered any case against it.

XeTeX, and the situation with encodings and fonts that led to its development, are introduced in the XeTeX Companion, which is in the Documentations folder.

Both *Memoir* and the *Not So Short Introduction* suggest XeTeX and provide a gentle initiation to the underlying ideas and application.

BiBTeX

LaTeX probably became a truly powerful typesetting system for academics with the advent of BiBTeX, an in-built program that produces bibliographies. The bibliographies are produced from a library of citations, a citation style, and the corresponding citation keys that are in the document.

There are a few ways to go about citations, as explained in *Memoir* and the *Not So Short Introduction*. However, the most common way of approaching citations and bibliographies appears to be either BiBTeX, or a direct descendant of BiBTeX that has introduced another facet of compatibility.

My impression is that BiBTeX can seem more complicated than it is, at first, because it involves working with different files. But once the pieces are brought together it is just as concise as any other method.

It is not yet clear to me whether one single descendent of BiBTeX is best option, but I get the impression that they are very similar to BiBTeX. I have provided the documentation to BiBTeX in this repository. While originally written in 1988 and with documentation updated in 2010, BiBTeX is still maintained (if it ever does become obsolete, it will be easy to use one of the descendents, such as BiBLaTeX.)

The *Not So Short Introduction* suggests BiBLaTeX (which is invoked by loading the biblatex package). I found this easy to use. The documentation for biblatex is also provided in the repository.

Other Documentations

At this point, I feel that the main resources for learning L^AT_EX have been provided. However, specific requirements will bring up the need for more specific information.

Packages have been written to cater for certain needs, and each one comes with its documentation. I encourage you to at least have these on-hand when you go into some specific area, as it is important to remember that packages are add-ons, and may even clash with some functionality that you are drawing on elsewhere; or there may be some similar nuance to their use.

As mentioned above, the bibliography for the *Not So Short Introduction* is effectively a list of common packages.

- for Tables:
 - tabularx package
 - array package

Chapter 3

Official Sites

The LaTeX Project

This is the official website of LaTeX in that it is the website of the project responsible for maintaining the entity of LaTeX.

<https://www.latex-project.org/>

However, the project funds are actually administered by the Tex Users Group.

Tex User Group

<https://www.tug.org/>

This more informal looking website is possibly the most official base for LaTeX and TeX that there is online.

The Tex Users Group is the administrator of the LaTeX Project.

The Comprehensive Tex Archive Network

<https://www.ctan.org>

Example of things you would go to this site for are font catalogues, documentation downloads, and mirrors for packages. It functions as a kind of repository for the TeX Users Group.

Chapter 4

Online Help

There are a few places you can go for help online, including tutorial websites and forums. There are only a couple of places I recommend. In terms of tutorials, Overleaf (mentioned above) can be a good resource. As for forums, Stack Exchange is the only one that seems to be staying relevant.

<https://tex.stackexchange.com/>

Visit Stack Exchange with caution. Many of the answers are excellent, and many are quite terrible.

I have found the longer documentation for LaTeX to be much more useful than any of the shorter online resources. Online help has been crucial for me, but I have also been through a phase of bad habits, formed by picking out bits and pieces without proper guidance.

I have to admit that my main limitation is not being comfortable in the digital sphere. Too many things seem arbitrary. It is like a world where acronyms abound, without knowledge of their meaning being essential to aptitude. It could be that I prefer referring to written documents, rather than other media, so that I can process the assumptions behind each piece of information. I have not yet found YouTube to be a great resource on LaTeX, but others may get on well there.
